Indiana County Population Projections: 1995 to 2030

Preface

The future of our state depends on the wise decisions of its citizens. Information, based on solid research, is critical to those decisions. For this reason the Indiana University School of Business has been providing analyses of the past, insights into the present, and visions of the future since 1925.

These population projections are part of a continuing effort begun in the mid-1960s by the Indiana Business Research Center (IBRC), an integral part of the School of Business. In cooperation with state agencies, the IBRC offers projections of the population in each of Indiana's 92 counties twice each decade. This 1993 Series incorporates the results of the 1990 Census of Population, blended with data from the Indiana State Department of Health on births and deaths over the past decade. We are indebted to Susan Dorrell at the Department of Health for her continuing assistance in these efforts.

The 1980s were a time of dramatic population changes in our state. A major recession, followed by massive restructuring of key industries influenced the migration of thousands of people in Indiana. Suburban counties grew and many rural counties declined. Attitudes toward child-bearing changed and the opportunities for extending life were enhanced.

What lies ahead? What will be the geographic distribution of population among our counties? What age distribution can we expect? These questions are critical to the capital investment decisions of the public and private sectors. Decisions concerning education, health care, electric power generation, housing, transportation, communications and social services all depend on the location and nature of our population. These pages provide a uniform view of that future within a context of continuing study of our state's population.

The IBRC is engaged in population studies on a full-time basis. These projections are not the result of an isolated activity, a quixotic venture. They are part of a continuing program supported by the Indiana General Assembly and administered efficiently by the Indiana Department of Commerce.

In addition to these projections, our program generates annual estimates of the population, frequent analyses of population changes and trends, and support for governmental units which use population data. This program of population studies has established a statewide network of professionals in many fields who meet several times each year to review population matters affecting Indiana. The IBRC represents the State to the U.S. Bureau of the Census and acts as a conduit of information between that federal agency and our state institutions.

This comprehensive approach to population studies was conceived by Dr. Robert A. Calhoun while on the staff of the Indiana State Board of Health. Dr. Calhoun, now retired, continues to provide guidance for our efforts and to be a valued chairman of the Indiana Population Working Group.

The efforts which produced this 1993 Series of population projections were distributed over a number of persons working together at the Indiana Business Research Center. Each individual contributed an important part of the final product. Data inputs had to be gathered and processed. Alternative projection methodologies had to be studied, accepted or rejected, and put into effect. Reports had to be generated which communicated the results in a clear and useful fashion.

The primary burden of coordinating and producing these projections fell to Susan Brudvig who stepped in at a critical moment and assumed responsibilities, perhaps beyond her expectations. The excellent result of her patient endurance is in your hands.

Projections are no more than a set of numeric computations based on the past and another set of key assumptions about the future. Will the next generation have different fertility experiences from the current population? Will medical progress lengthen life expectancy? Will economic bonanza or disaster befall the state? Only powers greater than our own can answer these questions. What we can do is present all of our assumptions as clearly as possible and detail the results.

The future certainly will not be as represented here. Events will intervene to cause future researchers to describe our "errors." But we believe these projections to be the best available. They are based on a consistent data set of the highest quality we could assemble. They involve the minimum number of assumptions about the future of our state. They can be understood and used because we offer a team of professionals prepared to help integrate these projections into the planning processes of public and private organizations.

This series of projections is scheduled to be updated and revised in 1998. Should dramatic events warrant a revision sooner, we are prepared to offer new projections. If other levels of detail beyond age,sex, and county of residence are required, please call us at 812-855-5507. We will be pleased to help within the constraints of our knowledge and resources.

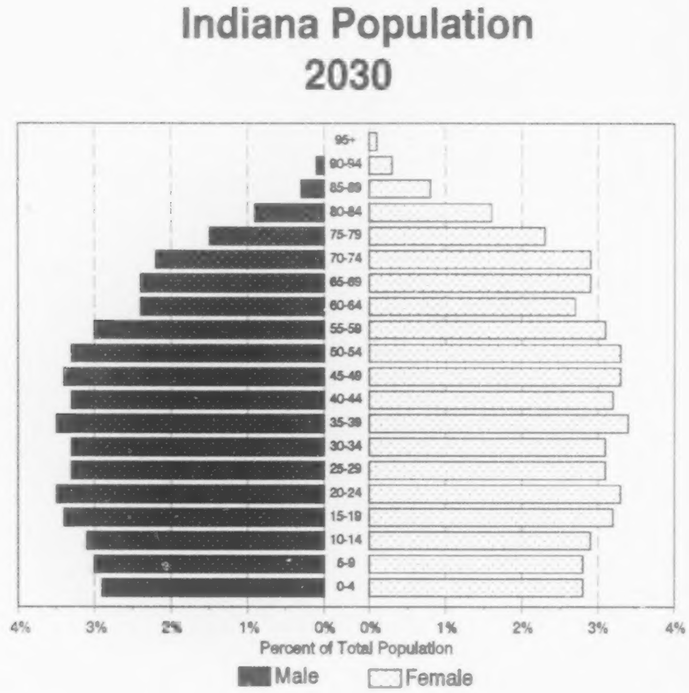
Table of Contents

Section One
Overview 1-18
State and county population trends

Section Two
County Projections 19-204
Two pages of graphics and data for each of Indiana's 92 counties and the state

Section Three
Methodology 205-216
A review of the methods used to produce the 1993 series

Appendices 217-220



Section One

Overview

State and county population trends

Population Change

Indiana's population will grow from 5.54 million in 1990 to a projected 5.92 million in the year 2020, a 6.7% increase. Between 2020 and 2030, the state's population will decrease slightly to 5.88 million, a 0.6% decrease.

By the year 2000, Indiana's population is expected to reach 5.7 million, a growth of 158,900 people and a percentage gain of 2.9% since 1990.

Figure 1. 130 Years of Indiana Population

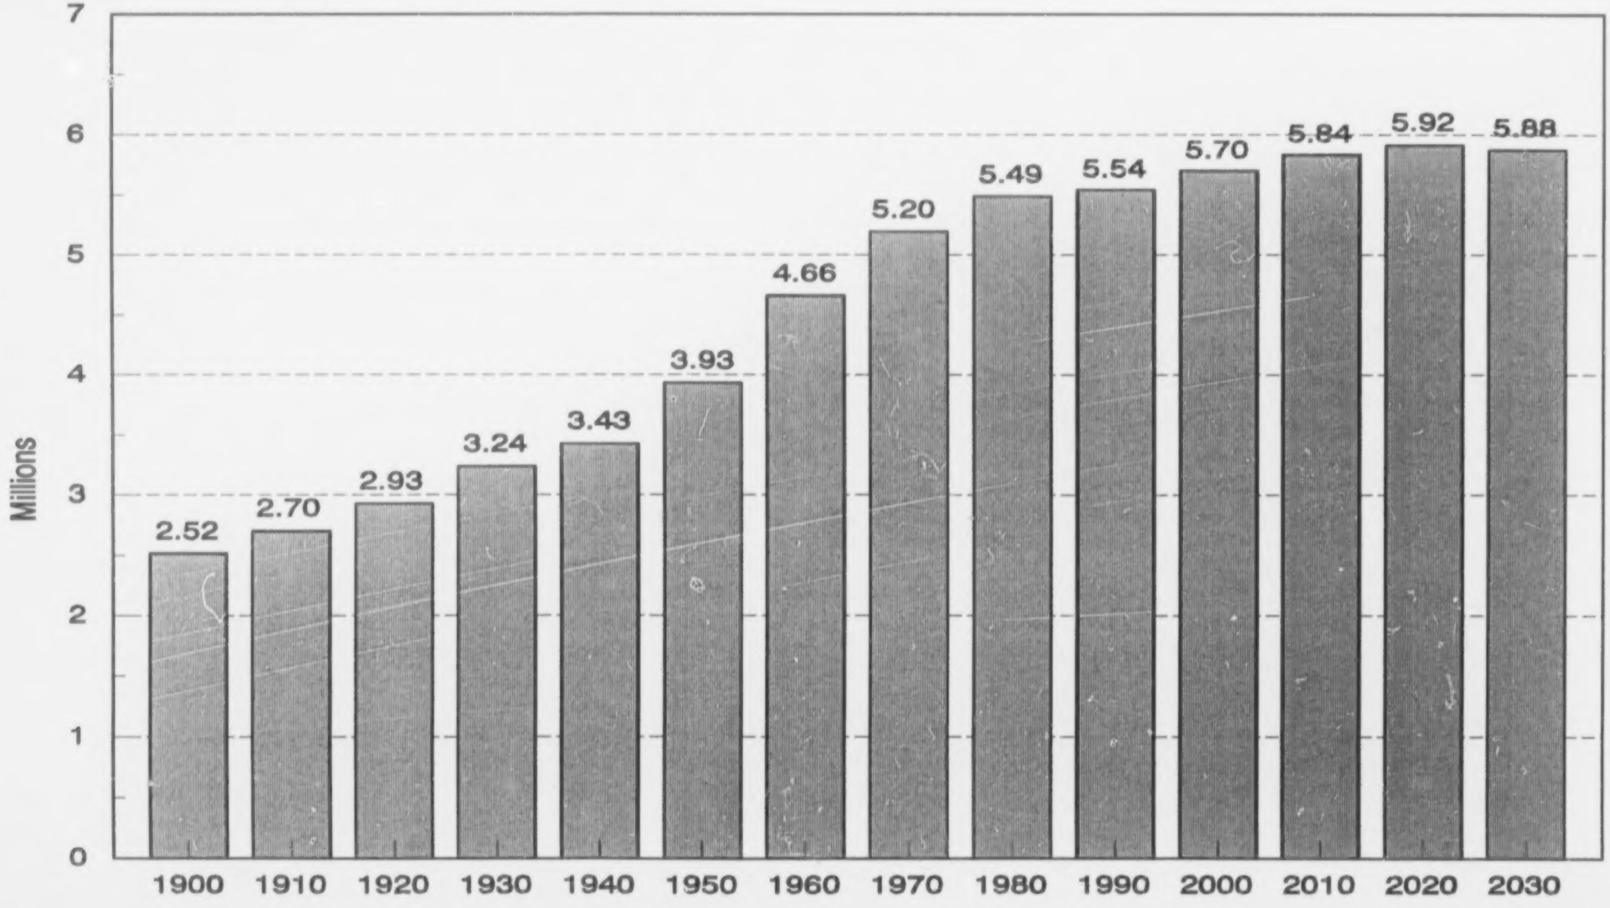


Figure 2. Change (bar) and Percent Change (line) in Indiana's Population: 1900 to 2030

The gains in population in the coming decades will seem small compared to those experienced prior to 1980.

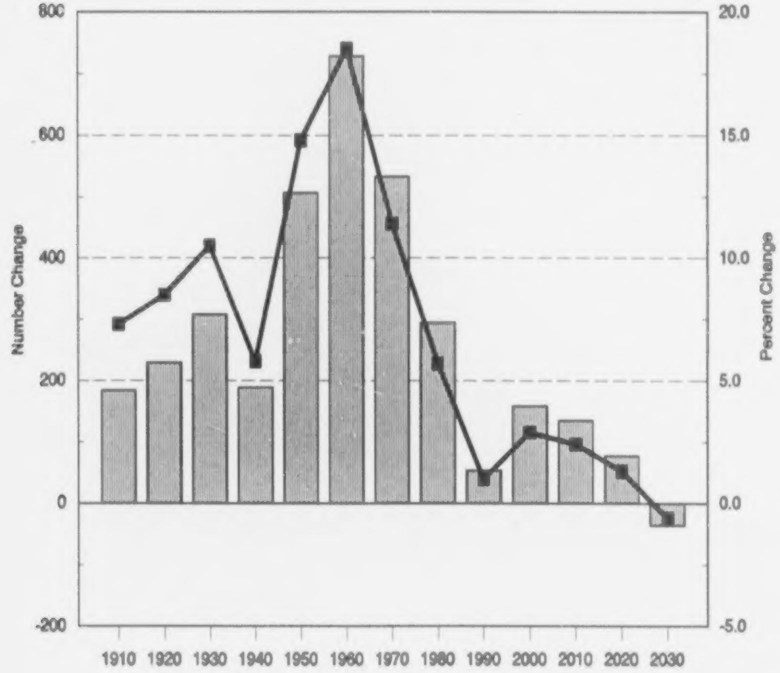

Figure 3. Indiana's Population Change: 1995 to 2030

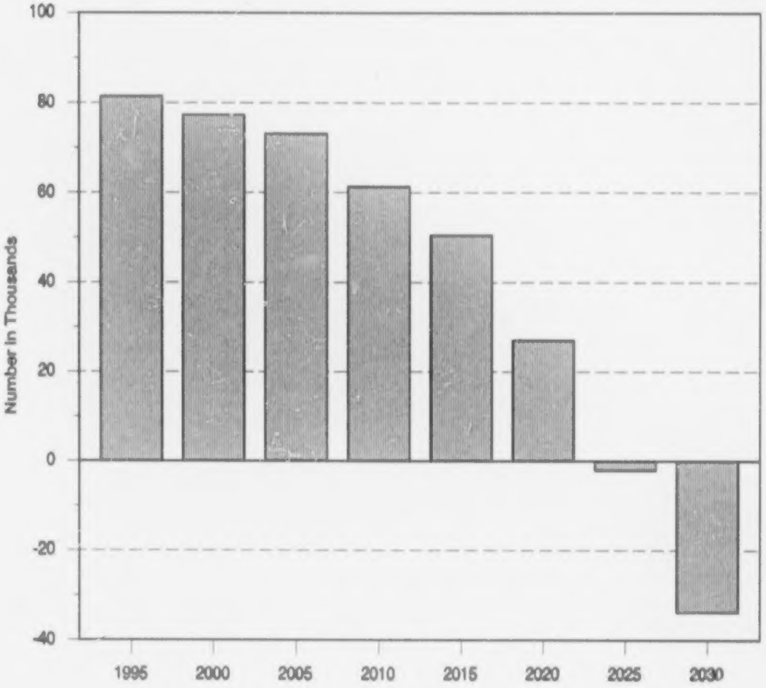
Between 1990 and the year 2020, the population of Indiana will increase by 370,800. The decrease expected in the following decade will be only 35,900.



Fifty-eight counties will gain population between 1990 and 2030, while 44 counties will see a decline.

From 1990 to the year 2030, the counties with the biggest numeric gains in population will be Marion, Allen, Elkhart, Hamilton, and Tippecanoe. Those counties with the biggest losses of population will be Grant, Madison, Vanderburgh, Vigo, and Clark.

Marion, Lake, Allen, and St. Joseph will continue as the four largest counties in Indiana. By the year 2000, Elkhart will surpass Vanderburgh in size, becoming the fifth largest county in the state. By the year 2030, Tippecanoe, Hamilton, Delaware, and Monroe will be among the ten most populous counties, while Madison and Porter counties move out of the top ten.

Over the next forty years, the counties with the biggest percentage growth in population will be LaGrange (64.9%), Adams (40.8%), Hamilton (27%), and Kosciusko (23.9%). Those counties with the biggest percentage loss will be Grant (-15.1%), Warren (-14.8%), Vermillion (-13.8%), and Henry (-12.1%).

Ohio, Switzerland, Union, and Warren are projected to remain Indiana's least populous counties during the period.

Thirteen counties are projected to grow more than twice as fast as Indiana (2.9%) between 1990 and 2000. These will include Hamilton (17.3%) and LaGrange (14.7%).

In 1990, 22.5% of Hoosiers called Marion or an adjacent county their home; by 2010, it will be 23.5%.

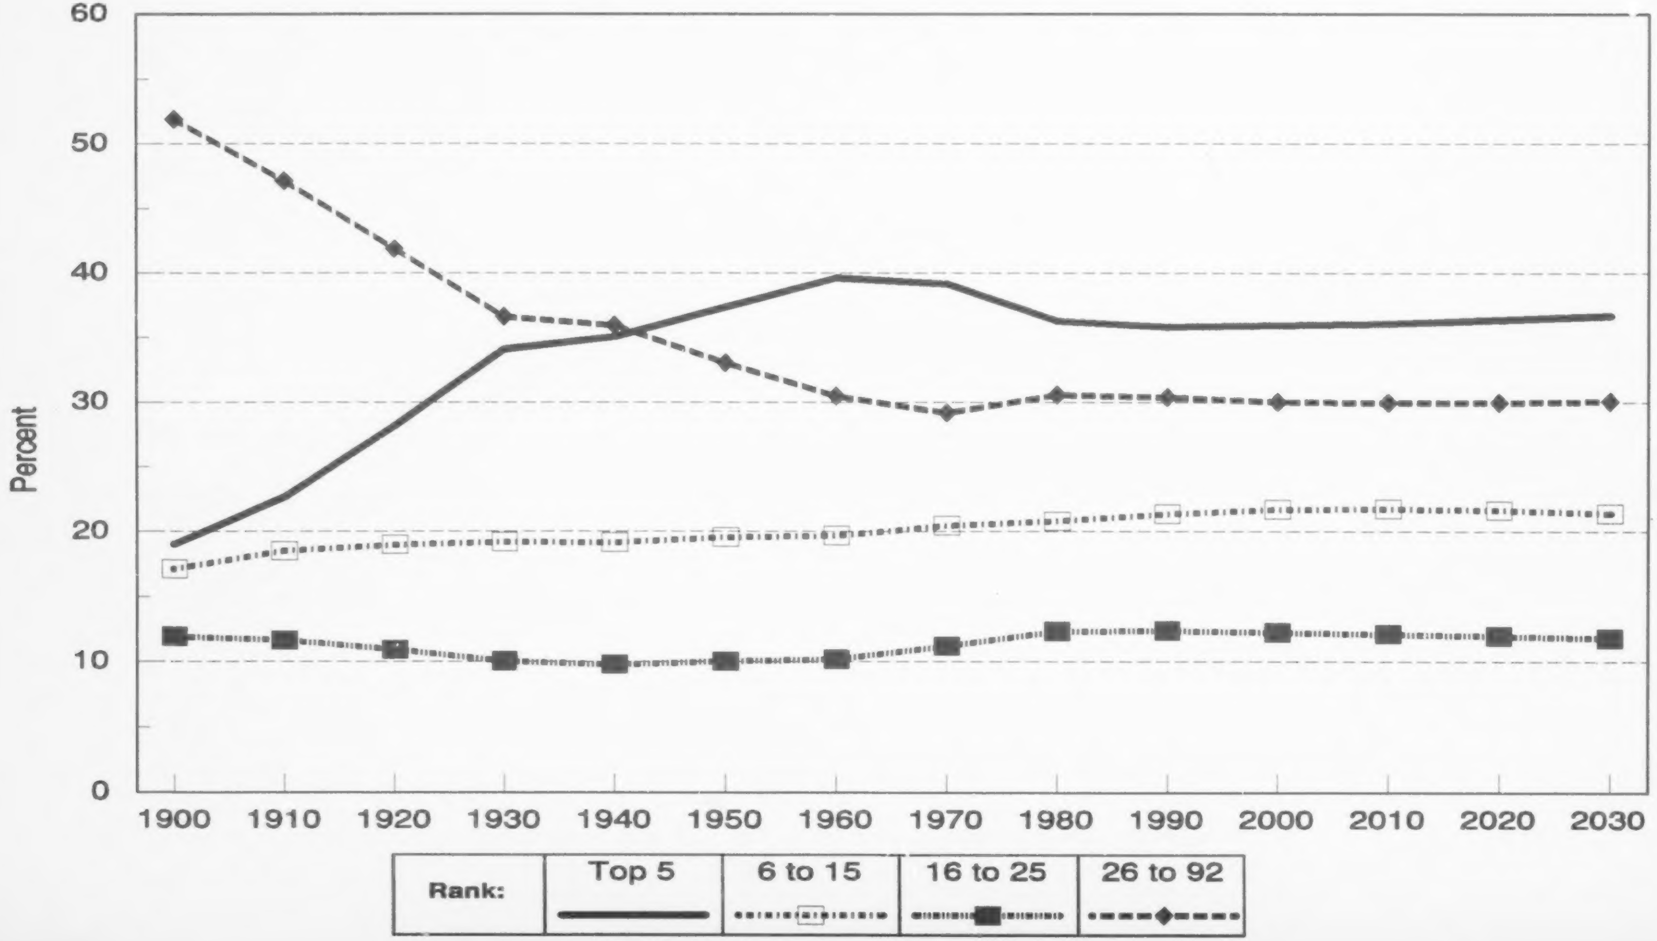
At the beginning of the twentieth century, Indiana's five largest counties had less than 20% of the total population, and Indiana's 25 largest counties had about 50% of the total. By 1960, the five largest counties had nearly 40% of the total population. The next 20 counties in size had only a modest increase in share. The top 25 counties' share rose to nearly 70% of the state's population, a share which remains basically unchanged through the year 2030.

Figure 5. Share of Indiana's Population by Size Ranking of Counties



Population by Age

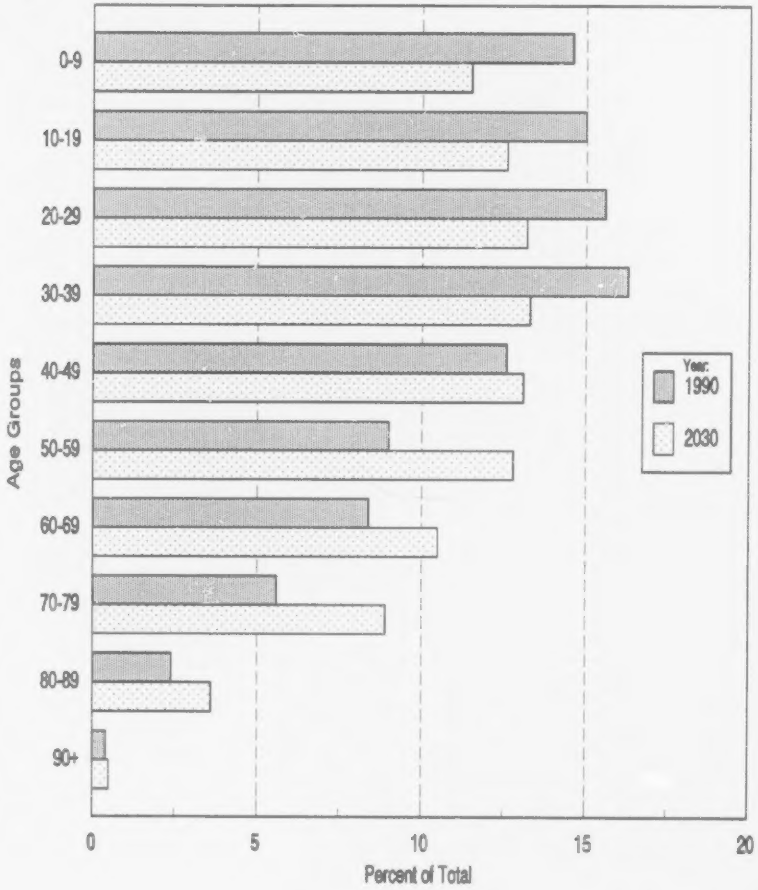
The percentage of Indiana's population under age 40 may never again be as large as it was in 1990, 62%. This population is projected to drop to 57% of Hoosiers by the year 2000, to 55% in 2010, and to 51% by 2030.

Between 1990 and 2030, the number of children under age 18 will decrease from 1.46 million to 1.26 million. The population of an age (18 to 21) to enter college, the military, or the labor force is expected to decline by 2% between 1990 and 2000. Over the next 40 years, this age group will continue to shrink.

Baby boomers will reach their retirement years between 2010 and 2030, and Indiana will see substantial increases in its older population. In the year 2010, there will be nearly three-quarters of a million people aged 65 and older; by 2030, nearly 1.1 million. Between 1990 and 2000, those aged 40 to 59 are expected to increase by 302,600 or 25%.

Hoosiers 65 and older are expected to increase in number faster than the population as a whole. In 1990, this group comprised 12.6% of all Indiana citizens; by 2030 it will comprise 18.4%.

Figure 1. Percent Distribution by Age: 1990 and 2030



Each age group under forty declines in population between 1990 and 2030; the aggregate of these decreases is 437,200 persons.

Each age group over forty increases and the aggregate of these increases is 772,100. The net change is 334,900 persons.

Figure 2. Change in Indiana's Population by Age: 1990 to 2030

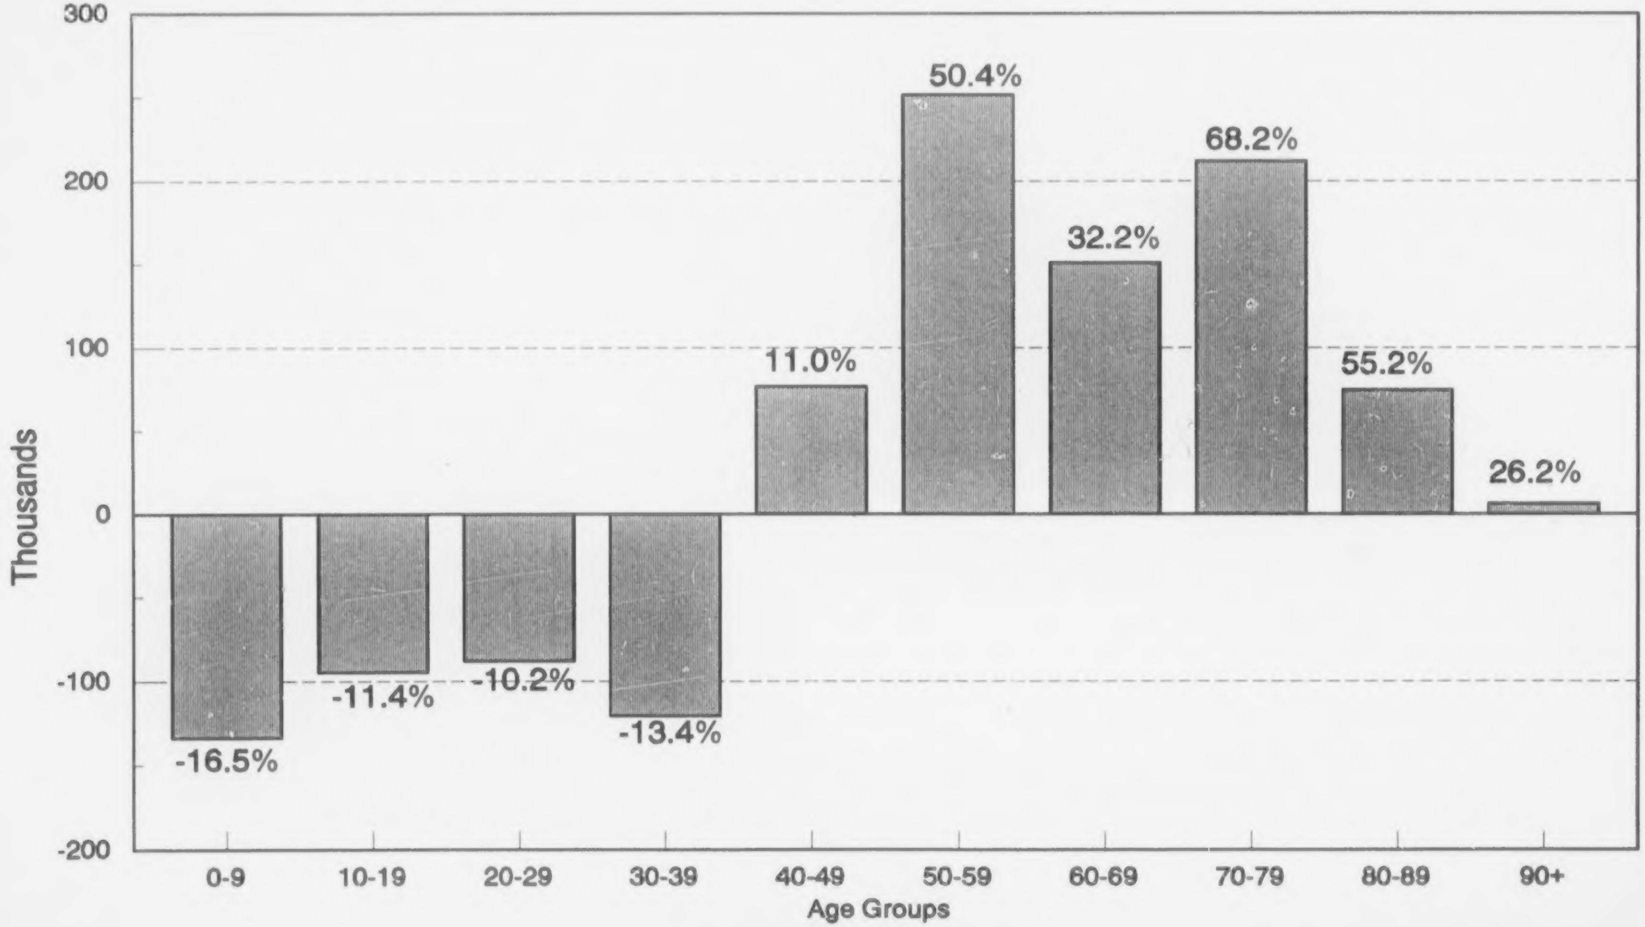


Figure 3. **Percent of Total Population by Decade for Ten Age Groups**

One of the most important changes for Indiana in the coming decades is the restructuring of the age distribution of the population. The social and economic implications are to be found by examining these changes decade by decade.

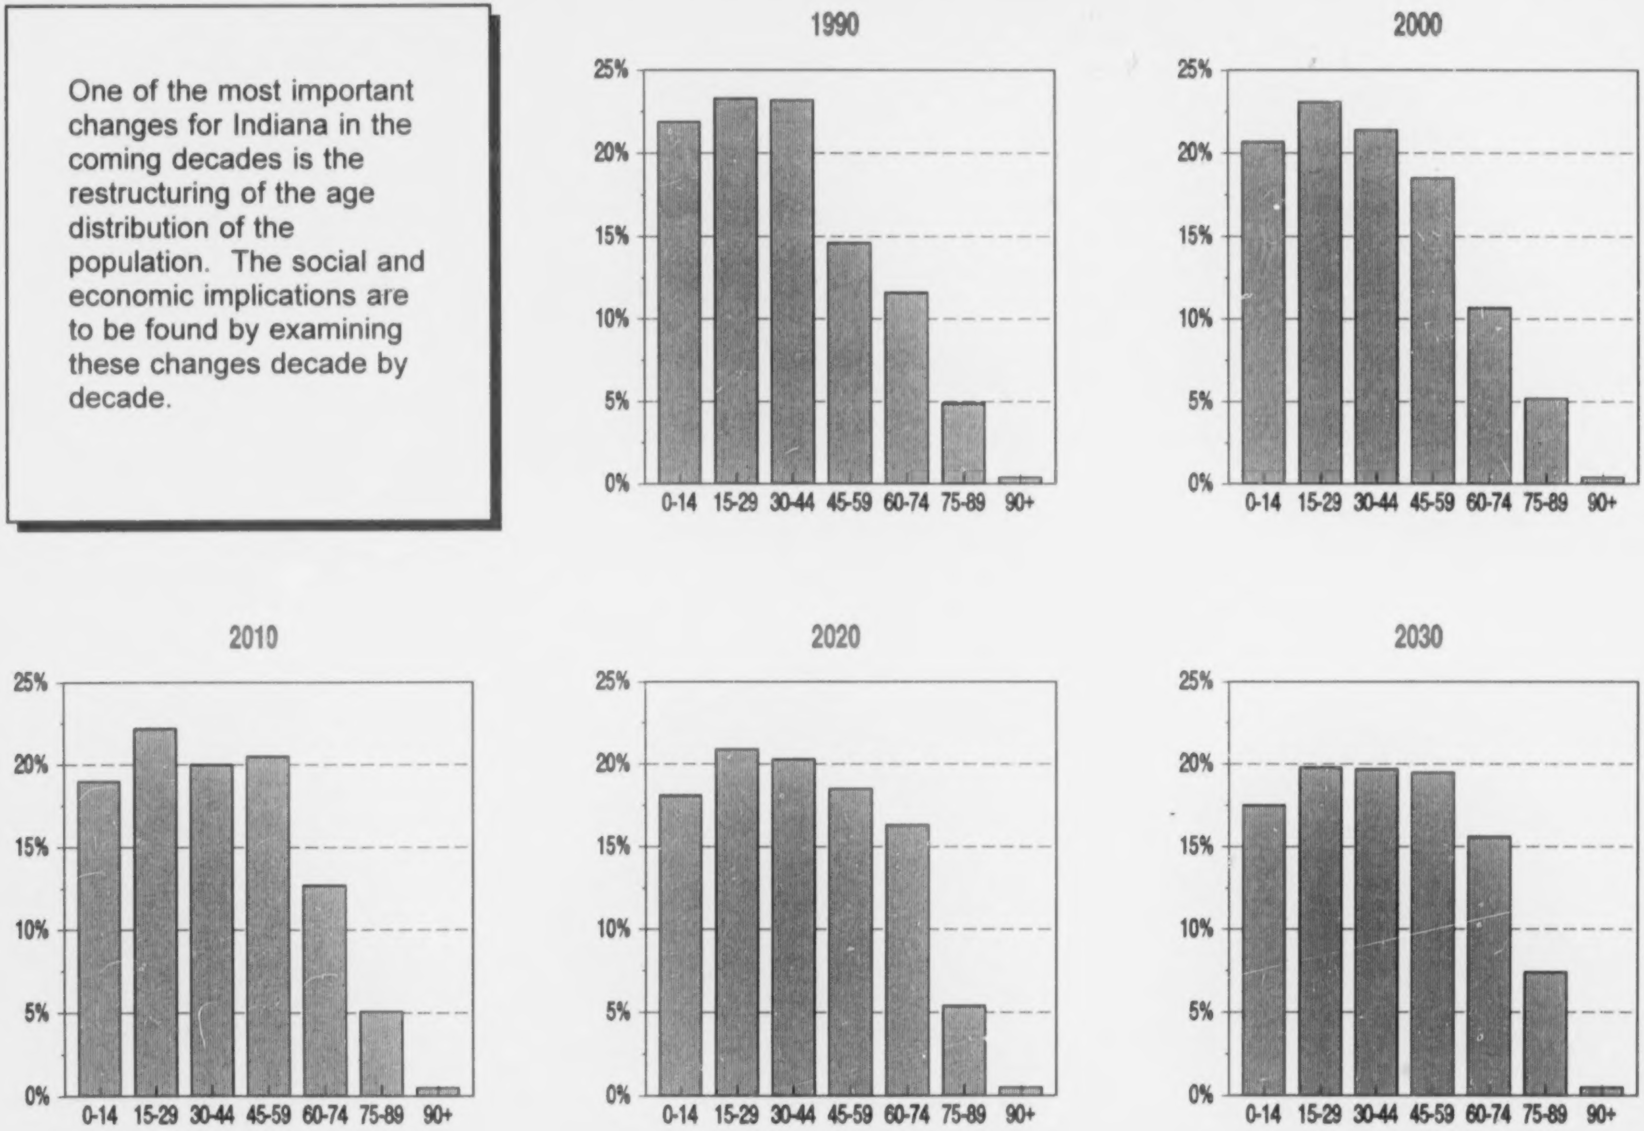

Figure 4. Indiana Population by Age: 1970 to 2030

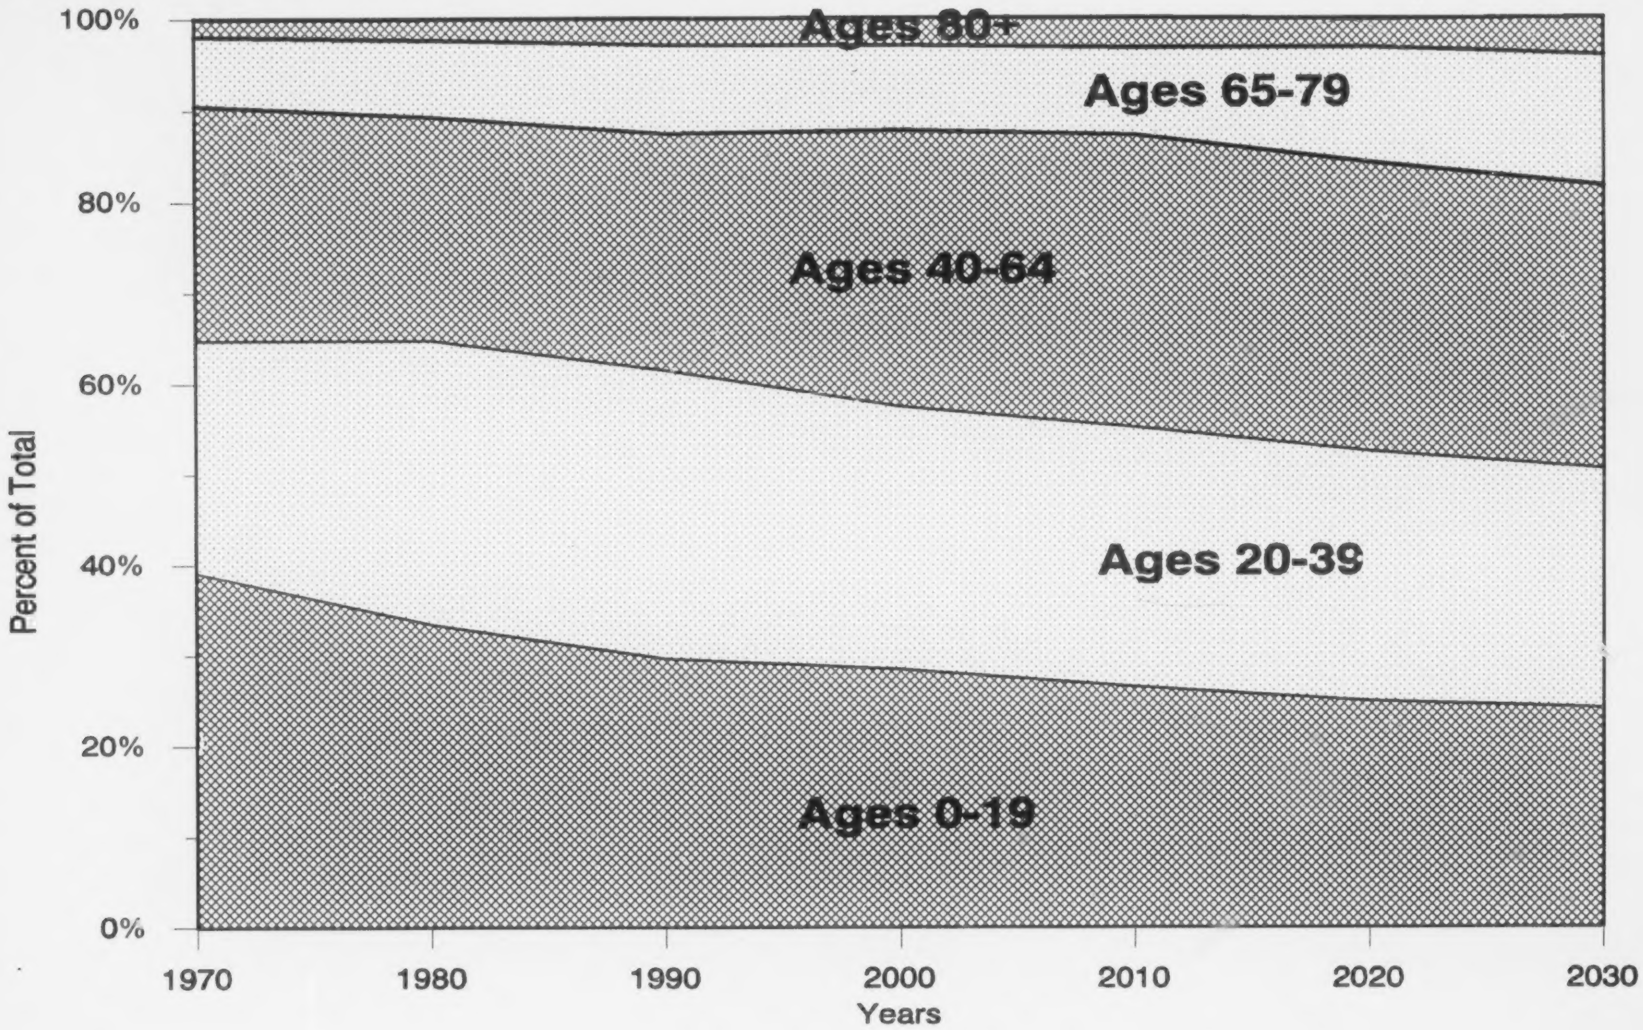

Figure 5. Change and Percent Change in Indiana's Population by Age

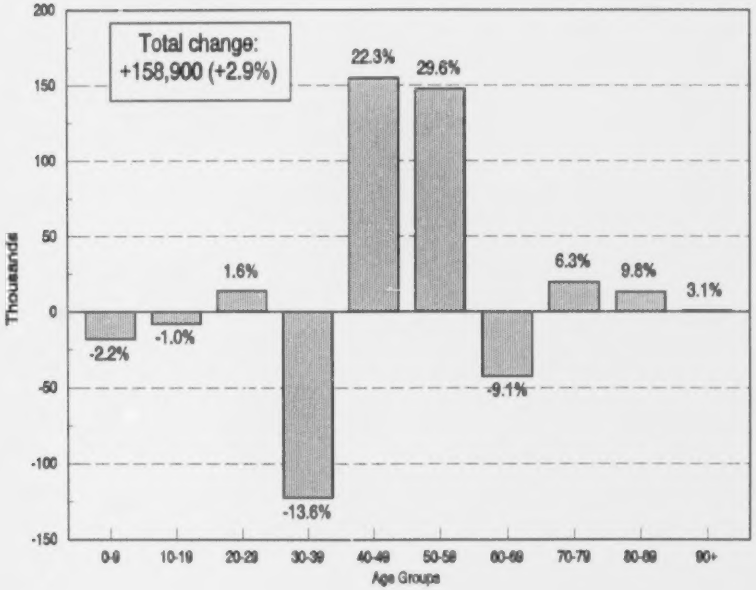
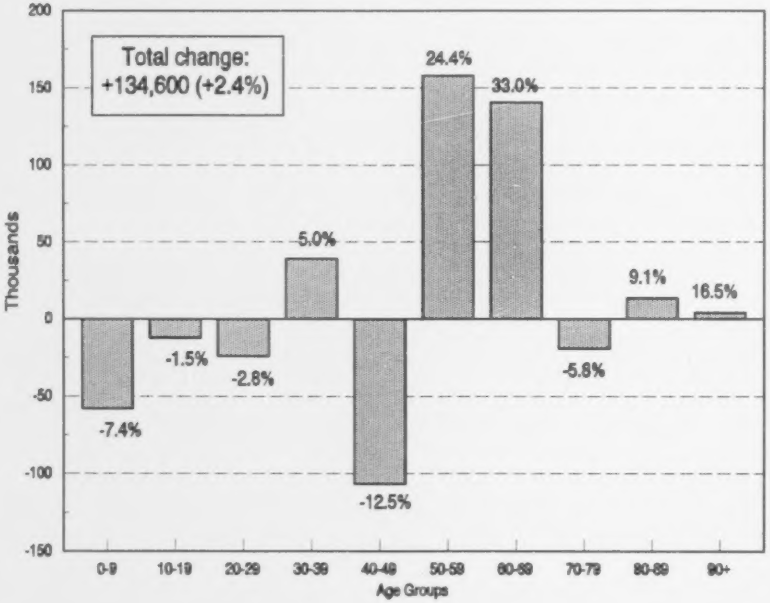
1990 to 2000

In the 1990s, the major growth in markets for goods and services will be for persons aged 40-59. Businesses and organizations will have to focus on a mature population, largely in the labor force, while experiencing a decline in the demand for those goods and services normally attractive to those in their thirties. The population under age 20 during this decade remains basically unchanged.



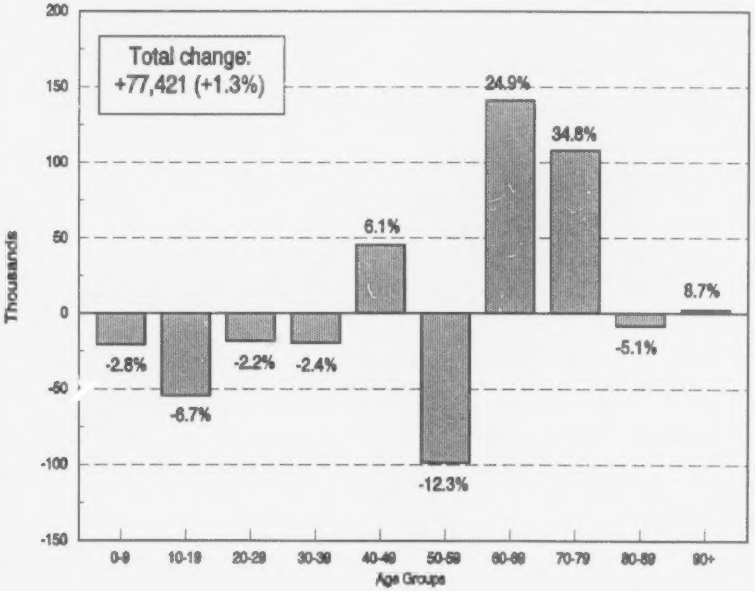
2000 to 2010

In the first decade of the 21st century, the major gain is in the population aged 50-69, when people are relieved of some of their obligations for a younger generation and focus more on their own retirement needs. The projections show a decline of more than 100,000 persons in their 40s, people who tend to be new, innovative managers. The percent increases in the population aged 80 and older become significant, and there is a notable decrease in the population under age 10.



2010 to 2020

During the decade starting in 2010, the baby boom reaches retirement years, impacting businesses and government agencies serving the population aged 60 and older. The total population of this group increases by 243,600. At the same time, the population aged 20-59 declines by 91,200 and there is an additional decline of 75,000 in the population under age 20.



2020 to 2030

In the final decade of the projection period, the total population declines. However, increases are still found in the population aged 70 and older, an age group that becomes increasingly dependent on the working age (20-69) population, which decreases by 137,900. At the same time, the population under age 20 continues to decline.

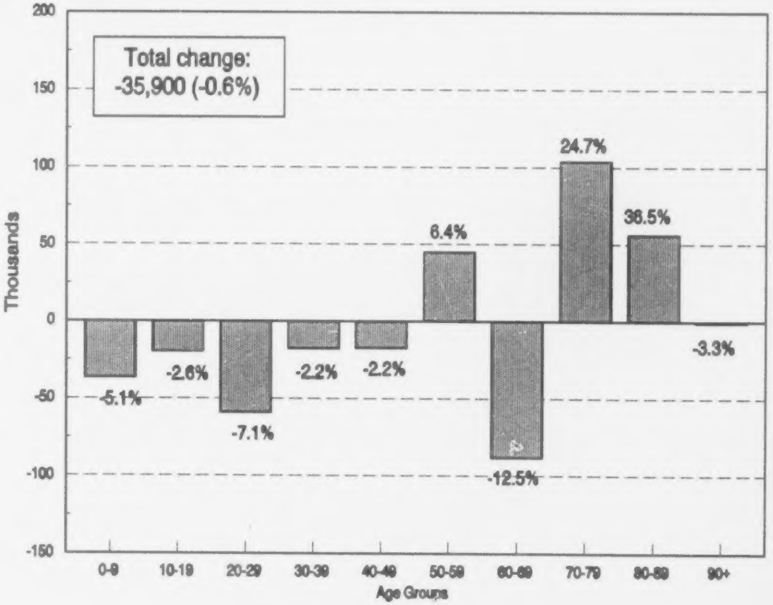


Figure 6. Indiana's Median Age: 1970 to 2030

The greatest change in median age came between 1980 and 1990. In the 1990s, the aging of the population will slow somewhat. Between 2000 and 2020, the change in median age will be comparable to the change witnessed in the 1970s.

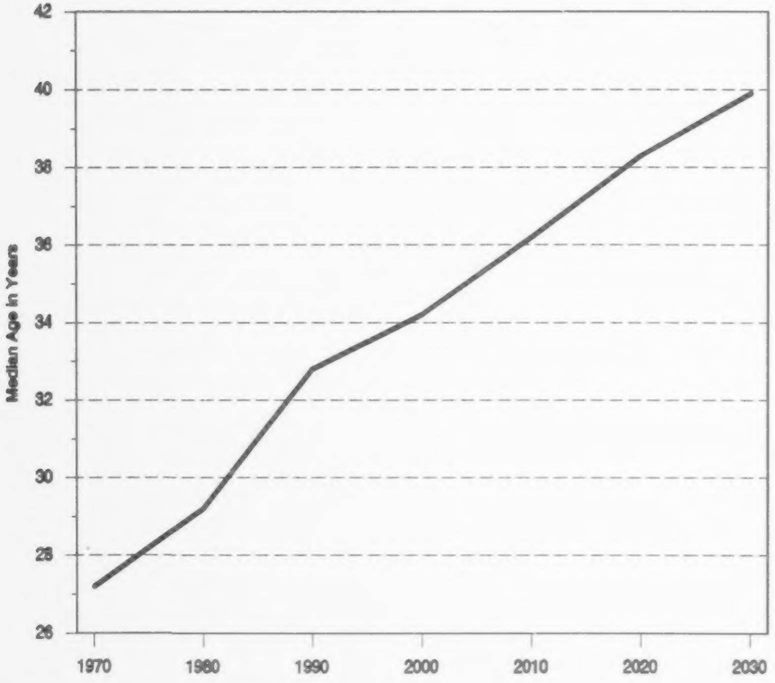

Figure 7. Change in Median Age by Decade

The aging of the population is shown quite clearly by the projected increase in Indiana's median age. By the year 2030, the Hoosier median age will be 39.9 years, an increase of 7.1 years over the 1990 median of 32.8.

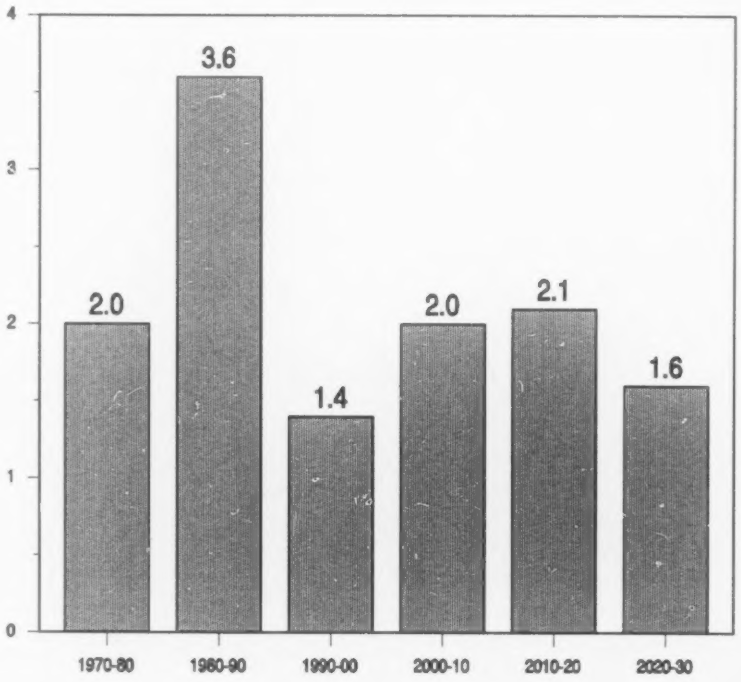

Figure 8. Median Age by County in 2030

The median age for all Indiana counties will steadily increase by the year 2030. The median age in four counties will increase by at least ten years between 1990 and 2030: Porter, Johnson, Washington, and Hamilton. The youngest Hoosier counties, between 1990 and 2010, will be LaGrange, Monroe, and Tippecanoe, each having a median age of less than 30 years. Monroe and Tippecanoe have significant college-age populations, while LaGrange has the state's largest percentage of persons under age 18.

Below 39.9 (36 counties)

Figure 9. Change in Median Age by County: 1990 to 2030

Between 1990 and 2030, Indiana's median age will increase by 7.1 years, with 38 counties rising by that number or more. Fifty-four counties will age more slowly than the state. Since aging of the population is not taking place at the same pace through out the state, it is important for business and service agencies to recognize county differences in setting policies and strategies.

Below 5.5 (29 counties)

Components of Change

Populations change through a combination of births and deaths, plus the net effects of migration. When births exceed deaths, natural increase occurs. Although births and deaths can be projected, net migration can only be estimated (see *Methodology* in Section Three for details).

Beginning in 1990, the number of births in Indiana will slowly decrease from an annual average of 78,400 in the 1990s to 68,200 in the 2020s. Fewer women in their child-bearing years, most of whom will have fewer children, brings about the lower number of births.

The first year in which 50,000 Hoosiers died was 1991. From then on, it is likely that every year will have at least as many deaths. By the year 2025, more deaths than births will occur in Indiana and we will enter an era of natural decrease in population. If there had been net in-migration after 1990, Indiana's projected population would be larger than it is actually projected over the forty-year period.

Figure 1. Indiana's Projected Births and Deaths: 1995 to 2030

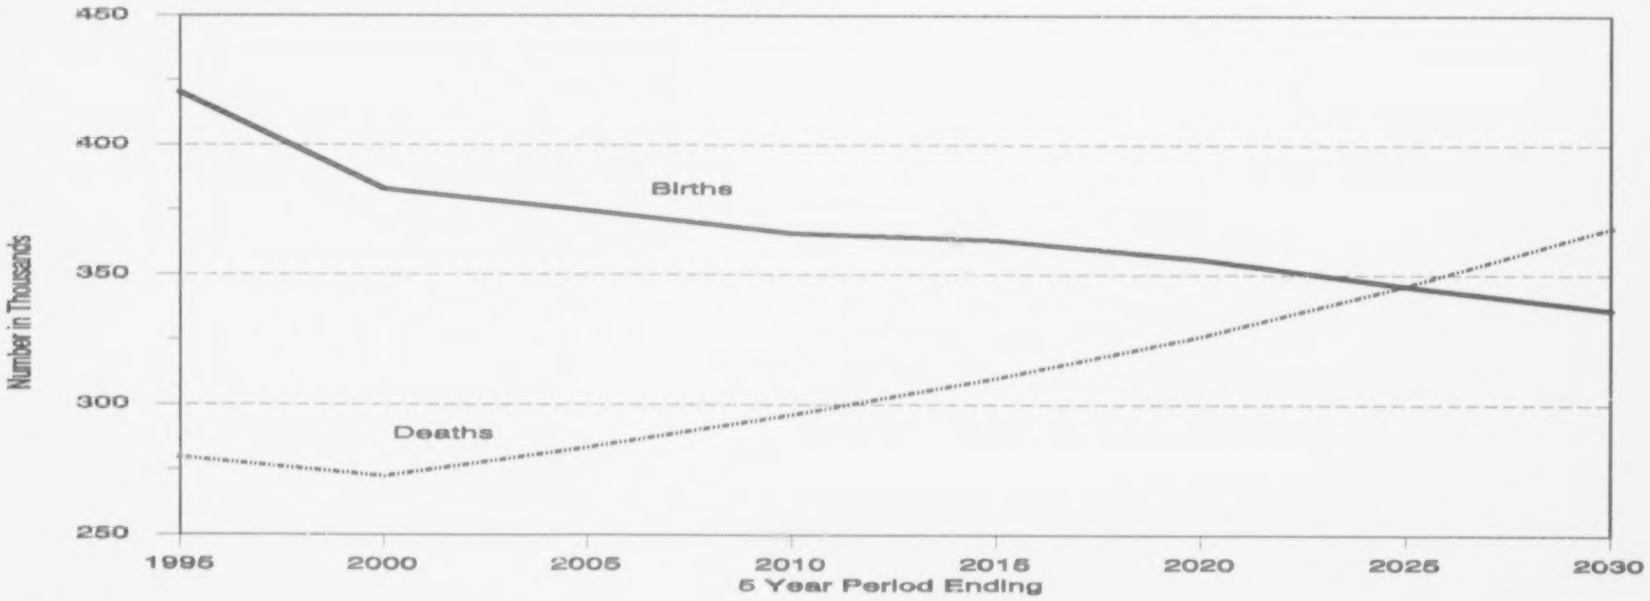

Figure 2. Counties in Which Natural Increase Continues Through 2030

Thirty-one counties continue to have more births than deaths throughout the projection period, 1995 to 2030.

Natural Decrease Occurs by the Decade Ending In...
2000 (6 counties)
2010 (14 counties)
2020 (21 counties)
2030 (20 counties)

Indiana's population continues to grow through the year 2020, as natural increase overwhelms out-migration. However, the level of natural increase declines, even though negative net-migration is also declining. In the last decade of the projection period, natural increase and net migration couple, producing a decline in the state's population.

Figure 4. Indiana's Natural Increase and Net Migration Patterns: 1995 to 2030

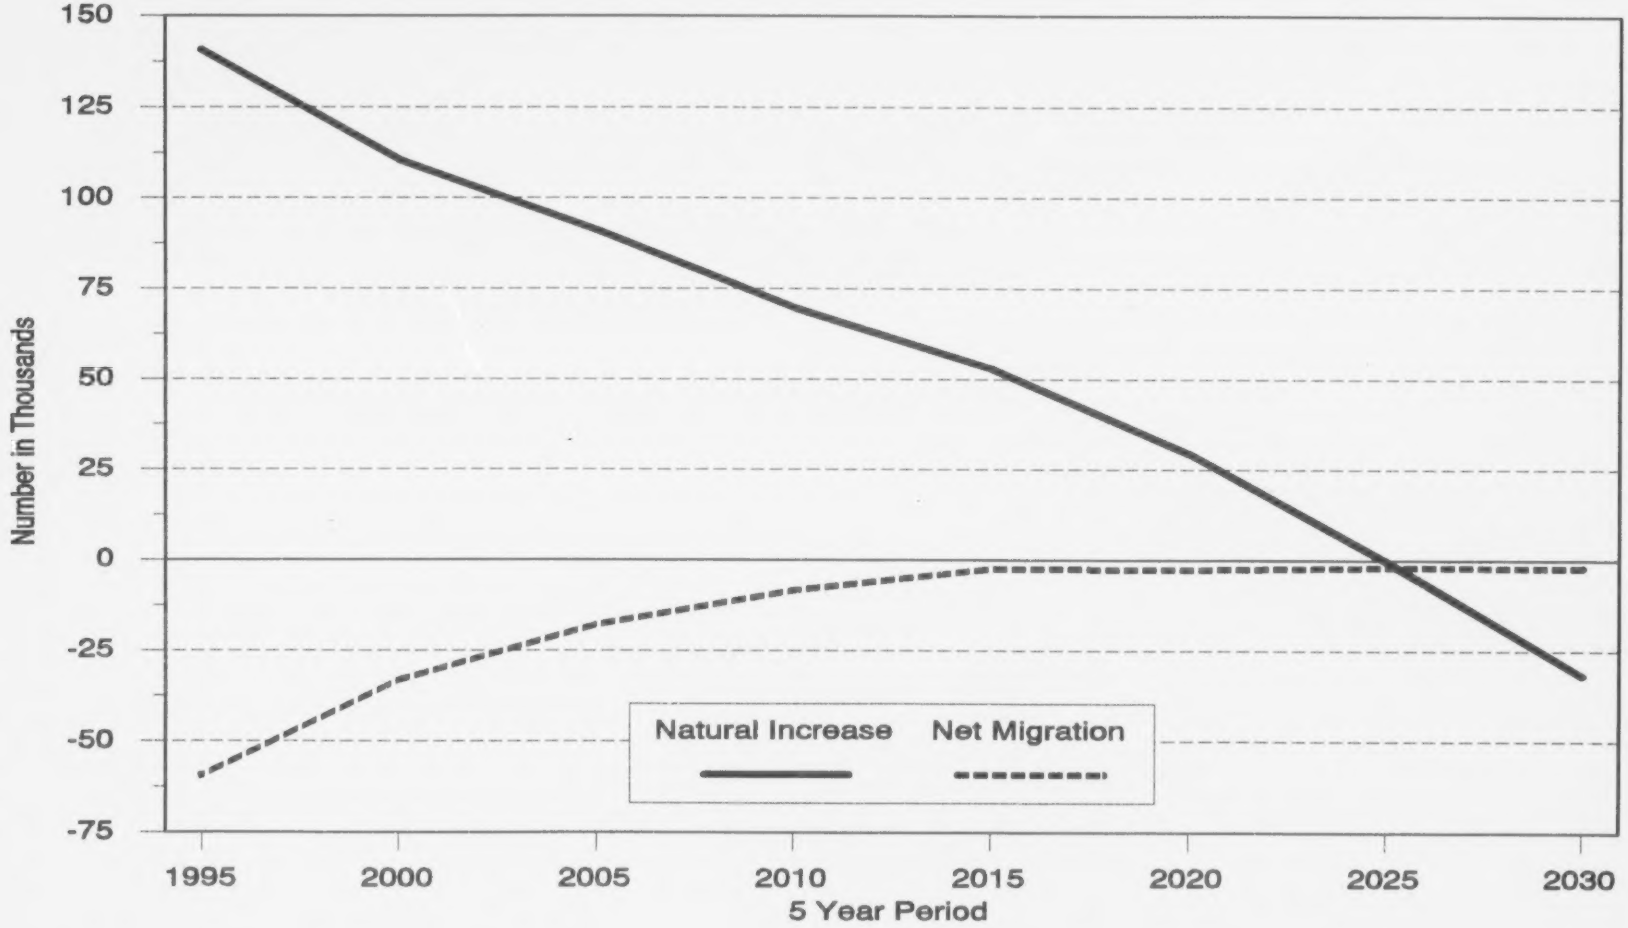

Figure 5. Counties with Increasing Population - Components of Change 1990 to 2030

Fifty-eight counties will increase in population from 1990 to 2030. In 15 of these counties, both natural increase and net in-migration are the factors contributing to growth. Only in Steuben county is net in-migration the dominant factor. In 43 counties, growth occurs because natural increase exceeds net out-migration.

Increasing Population where:
Natural increase is greater than net in-migration (14 counties)
Natural increase is greater than net out-migration (43 counties)
Natural increase is less than net in-migration (1 county)

Figure 6. Counties with Decreasing Population - Components of Change 1990 to 2030

Thirty-four counties decline in population between 1990 and 2030. In Brown, Putnam, and Switzerland counties the excess of deaths over births (natural decrease) outweighs net in-migration. In 22 counties, natural decrease and net out-migration work together to lower the population, with natural decrease the stronger force in two of these counties. Nine counties will experience net out-migration sufficient to offset the natural increase in population that will occur.

Section Two

County Projections

Two pages of graphics and data for each of Indiana's 92 counties and the state

Note:

Derivation of Percent Distributions of Selected Age Groups

Calculations for "functional age groups" (e.g. 0-5, 6-12, etc.) assume an equal distribution of persons within each five-year age group. Therefore, projections of persons in these age groups are not directly comparable to the 1990 Census, which uses single age data.

Rounding

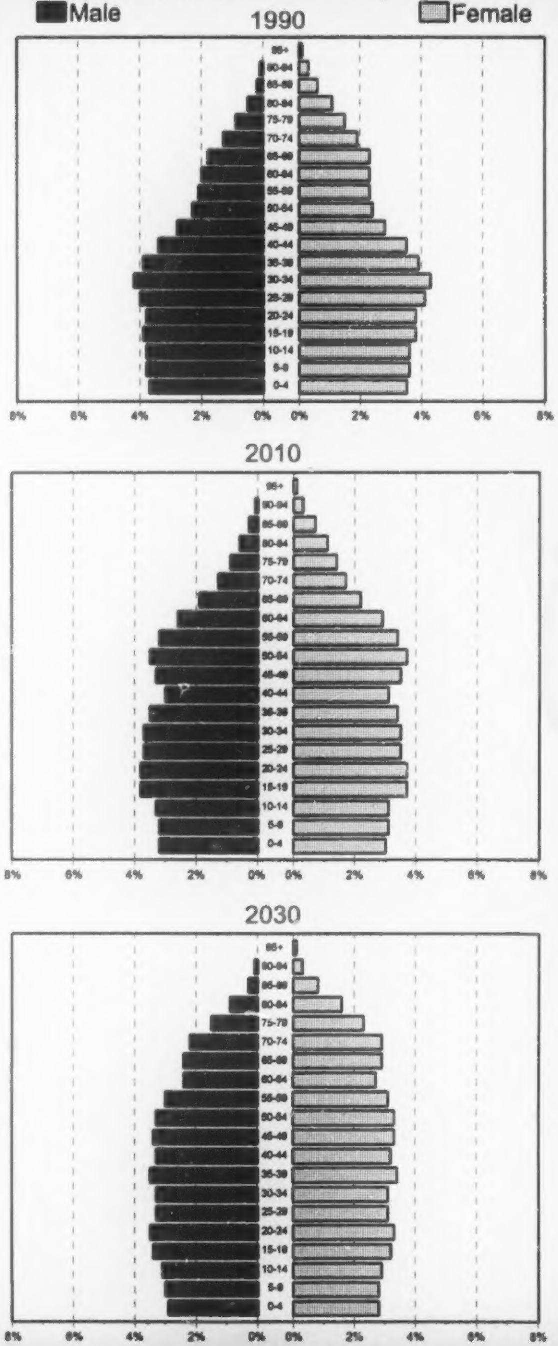
Except where otherwise noted, the figures in this report have been rounded independently from figures computed to the last digits. Hence, the sum of the parts may differ from the totals shown.

Indiana

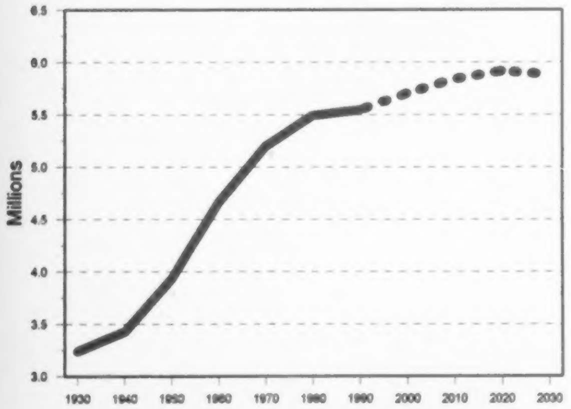
Indiana County Population Projections: 1995 to 2030

Produced for the State of Indiana
by the Indiana University School of Business,
Indiana Business Research Center

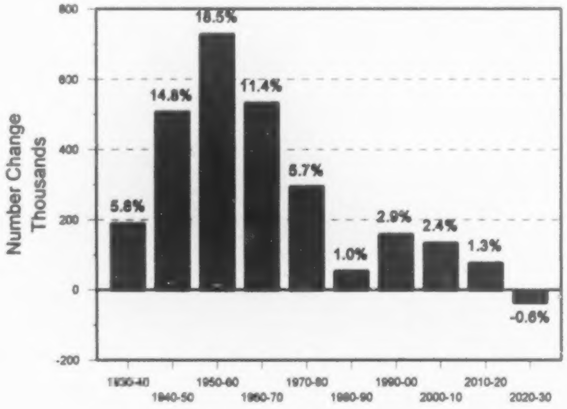
Percent of Total Population



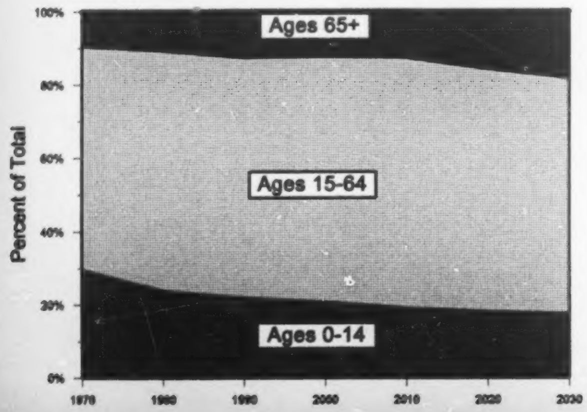
Population: 1930 to 2030



Population Change: 1930 to 2030



Major Age Groups: 1970 to 2030



Median Age: 1970 to 2030

Year	Indiana
1970	27.2
1990	32.8
2010	36.2
2030	39.9

Section Three

Methodology

A review of the methods used to
produce the 1993 series

Methodology

Introduction

This report contains projections of the population of Indiana and its 92 counties by age and sex for the years 1995 to 2030. The projections presented here supersede the information contained in *Indiana County Population Projections: 1985 to 2020* (Indiana Business Research Center, 1988). Although the basic framework is the same as in past projections, this edition represents a major advance in our county projection methodology. The 1993 edition represents the first set of county projections classified by functional age categories as well as by 5-year age groups. It is the first to project the following age groups: 85-89, 90-94, and 95 and older. Finally, it is the first to project the population to a July 1 date.

Cohort - Component Methodology

Cohort-component methodology was used to project the population of Indiana and its counties. For each five year period, the population is projected for individual age-sex cohorts and separately by the components of change -- mortality, migration and fertility. In contrast to extrapolative methods, the cohort-component method is preferred because it takes into account the dynamics of population change. It also produces highly detailed projections which users typically require.

The cohort-component method is based on the traditional demographic accounting system:

$$P_1 = P_0 + B - D + NM$$

where:

P_1 = population at the end of the period
P_0 = population at the beginning of the period
B = births during the period
D = deaths during the period
NM = net migration during the period

In order to generate projections using this model, data for each of the components are required: the base-year population, the base-year group quarters population, projected fertility rates, projected survival rates, and projected net migration rates.

In its simplest form, this method projects the population of the future by beginning with the population of the recent past. The base population is projected forward by applying survival rates, net migration rates and fertility rates. For example, in order to project the number of males, aged 15-19, we start with the number of males aged 10-14 in 1990, deduct the number of expected deaths and add the number of net migrants. To project the number of 0-4 year-olds in 1995, we add the number of births expected between 1990 and 1995, less expected deaths and plus net migrants (Haub, 1987). The procedure is iterative: the 1995 projected population becomes the base population for the projected population in 2000.

Base Population

The "jump-off" date for the projections is April 1, 1990, census enumeration day. The base population is 20 five-year age groups by sex for Indiana's counties. The data were obtained from the 1990 Census of the Population, Summary Tape File 2, U. S. Bureau of the Census.

The enumerated population was chosen as the base population in lieu of the Census Bureau's so-called MARS (Modified for Age, Race, and Sex) file. While the MARS file purports to correct for erroneous responses, particularly in the reporting of age by the youngest and oldest segments of the population, there were several reasons not to use it.

First, there is considerable debate among experts about the derivation of this file (see, for example, Shrestha and Preston, 1993). Second, our independent analysis of the MARS data for Indiana supports many of these contentions, calling into question the valid uses of the data. The third reason, and possibly most important, is that, in contrast to the census as enumerated, a complete series of MARS census data is available *only* on magnetic tape. Anyone using a set of MARS-based projections as controls in sub-county or sub-group projections would have to acquire comparable data at considerable cost.

The first projection cycle is five and one-quarter years, projecting the 1995 population to a July 1 date. Thereafter, all projection cycles are five year periods, and all populations are projected to July 1.

Group Quarters Populations

The calculation of any county projection requires special treatment of group quarters populations, those persons in college, prisons and military barracks, for example (Murdock and Ellis, 1991). These populations must be treated separately because their migration, fertility and mortality patterns differ from the household population (Pittenger, 1976). While the individuals may be replaced periodically, this population can be treated *as if* it does not change.

Generally, special populations are treated in one of two ways. One way is to develop county-specific patterns of fertility, mortality and migration. This technique may lead to the proliferation of highly idiosyncratic county models (Irwin, 1977). In addition, it tends to lead to complexity at the county-level, yet complexity is one characteristic which should be avoided (Pittenger, 1976). A second method of treating group quarters populations is to subtract the number of persons in group quarters from the base population *before* the components of population change are applied (see, for example, He, 1993). In effect, persons in households and persons in group quarters are projected separately.

This series of projections did not use one of the above methods in lieu of another. Instead, we used a combination of the two methods. For example, it was deemed necessary to use county-specific models of fertility, mortality, and migration. With sufficient controls placed on these projected rates, problems contributing to complexity are reduced. In addition, it is necessary to pay special attention to those counties with 5% or more of their total population in group quarters or with a group quarters population concentrated in a few age-sex groups. For these counties, plus-minus adjustments were performed which reallocated the projected group quarters population to its 1990 age-sex composition (He, 1992). The following counties required this type of adjustment:

Delaware
Grant
Hendricks
Jasper
Jefferson
Johnson
Knox
LaPorte
Madison
Monroe
Montgomery
Parke
Perry
Porter
Putnam
St. Joseph
Steuben
Tippecanoe
Vigo
Wabash

In addition, special modifications to the migration component were necessary for Marion, Delaware, Monroe, and Tippecanoe counties. These modifications are discussed below.

Finally, adjustments to group quarters populations were necessary in the two counties in which administrative decisions made after the 1990 census will impact the projected populations. First, 640 persons in group quarters were added to Sullivan County's 1995 projected population. Since 1990 the Wabash Valley Correctional Facility has opened, and 640 persons is the institution's capacity. Second, in Miami County, an adjustment was made to reflect the transfer of active military personnel from Grissom Air Force base to other locations. It was estimated that approximately 4,700 persons -- personnel, spouses, and dependents -- will leave the county between 1990 and 1995.

Projected Components of Change

This section describes the derivation of the projected rates of mortality, net migration, and fertility. The methods used to develop fertility and survival rates are heavily dependent on the recent work of Isserman (1993); the methods used to estimate net migration are heavily dependent on the classic work of Bogue et al. (1982) and of Shryock and Siegel (1971).

Death, migration and birth rates vary not only by age: they vary considerably by place. Therefore, the basic geographical unit in the construction of all rates is the county. As in the several previous projections, only one series of fertility, mortality and migration levels is presented.

Mortality

There is considerable debate among experts about the degree to which sub-state areas must have place-specific mortality models. While it is generally agreed that mortality varies by place, most projections assume that the statewide survival rates apply to any sub-state level (e.g., Price et al., 1992). In an effort to reduce the complexity of county-specific survival rates, attempts were made to classify counties by their mortality levels or by their "county character" (e.g., suburban, rural, etc.). For example, standardized death rates and mortality indices -- both conventional demographic procedures -- were developed for all counties. However, no consistent patterns were found among the counties, and no such classifications could be made. Nonetheless, it was concluded that the 1990 county-specific survival rates should be applied throughout the life of the series because there was sufficient variation among the counties to warrant the use of county-specific mortality models.

In order to utilize the cohort-component method, mortality data were required through 1991. Final death data by age, sex and county of residence were obtained from the Indiana State Department of Health. In addition, the number of persons in each age-sex group was required and was obtained from the Census Bureau. After the historical data were assembled, a number of procedures were used to generate the projected mortality component.

Deaths were averaged over a three-year period and then divided by the number of persons in each age-sex group. The period used in averaging must extend in equal intervals around the date of the population count. Since April 1 is the census date, a period extending five-quarters in each direction was used. For the weighted 1990 deaths, deaths occurring from January 1, 1989 through June 30, 1991 were used. Using these data, age-specific death rates for 1990 were calculated.

Survival rates were calculated directly from the death data: they are one minus the age-specific death rate. The five-year survival rate is the one-year survival rate raised to the fifth power. For infants born in the projection period, their survival rate is raised to the 2.5 power. The survival rates are operationalized to reflect the fact that an individual will, on average, spend 2.5 years in one age group and 2.5 years in the next. Because old-age survival has the potential to have a tremendous impact on the age structure of the state, survival rates for the oldest of the population were extended beyond the conventional 85-plus age group (Carter and Lee, 1992).

Net Migration

County estimates of net migration, 1985 to 1990, were constructed because recent data were not available. While the Internal Revenue Service does release county-to-county migration data on an annual basis, it lacks the age detail necessary for the cohort-component methodology. The migration data currently available from the U.S. Census Bureau is more than ten years old, and its next release is not scheduled until 1994.

The forward survival method of estimating net migration was chosen. The two other methods of estimating net migration -- the vital statistics method and census survival method -- were tested and deemed not appropriate for Indiana's counties. In particular, the vital statistics method should only be used for the total population because of the profound impact migration has on vital statistics (Pittenger, 1976). Census survival, while appropriate in some cases, assumes that a state's pattern mirrors the national one. Based on preliminary estimates of migration provided by the Bureau of the Census and the Bureau of Economic Analysis, it was concluded that not only does Indiana's pattern not mirror those of other states but that the state's recent migratory experience was far more favorable than anticipated.

In order to utilize the forward survival method, death data were required through 1991 and were obtained from the Indiana State Department of Health. In addition, the number of persons in each age-sex group in 1985 and in 1990 was required and was obtained from the Census Bureau. After the historical data were assembled, a number of procedures were used to generate the projected migration component.

A five-year operationalized, weighted, and averaged survival rate was applied to the county 1985 populations by age and sex in order to obtain expected 1990 populations. The expected population was subtracted from the 1990 census population, arriving at an estimate of residual net migration by age and sex for the period. The net migration rate was arrived at by dividing the estimate by the expected population. A county resident rate by age and sex was constructed; it is one minus the net migration rate.

In all but four selected counties, it is assumed that net migration will tend to zero. This was accomplished by applying a square root to the resident rates in each cycle, beginning in the 1990-1995 period. Special treatment of the projected migration component was necessary in Marion and the three college counties because of the historically age-concentrated migratory populations in these counties. In Marion County, no square root was applied to the resident rates until the 2000-2005 projection cycle. In Delaware, Tippecanoe and Monroe, the resident rates for the college-age population did not have a square root calculation applied.

Fertility

In order to utilize the cohort-component method, fertility data were required through 1991. Final birth data by age and county residence of mother were obtained from the Indiana State Department of Health. In addition, the number of women in each age group was required and was obtained from the Census Bureau. After the historical data were assembled, a number of procedures were used to generate projected fertility.

Total and age-specific fertility rates for 1980 and 1990 were calculated. Births were averaged over a three-year period and then divided by the number of women in households in the mother's age group. The period used in averaging must extend in equal intervals around the date of the population count. Since April 1 is the census date, a period extending five-quarters in each direction is used. For the weighted 1980 births, births occurring from January 1, 1979 through June 30, 1981 were used; for the weighted 1990 births, births occurring from January 1, 1989 through June 30, 1991 were used.

The total fertility rate (T.F.R.) is often recommended for projections (Raymondo, 1992). In addition to its simplicity, the T.F.R. simulates cohort experiences and implies future family size (Bogue, 1974). Therefore, the T.F.R. measure was chosen for establishing projected fertility. The future level of this component was set by trending each county's 1990 T.F.R.s to a 2005 target T.F.R. and holding the 2005 target constant thereafter.

Most analysts agree that future fertility levels will decline (Bos, 1993; Ryder, 1990; U.S. Bureau of the Census, 1991). Indiana's 1990 fertility levels are an upward fluctuation during a period of fertility decline For most of Indiana's counties, 1980 fertility levels represented an all-time low. Therefore, the projected fertility levels have been anchored by 1980 and 1990 birth rates: it is generally assumed that a county's total fertility rate will return to its 1980 level by 2005. For those counties in which the 1980 T.F.R. was higher than the 1990 T.F.R., the 1990 rate is held constant. For counties with T.F.R.s approximately the same in 1980 and in 1990, the 1990 T.F.R. is expected to decline by 5%, the anticipated state-level decline from 1990 to 2005. Counties which are outliers -- either have unusually high or low T.F.R.s or have unusually high rates of T.F.R. change between 1980 and 1990 -- required special treatment. The schedule of anticipated T.F.R.s appears in *Appendix A*.

With an established trend, the T.F.R.s anticipated for each projection cycle must be converted into an age-specific fertility schedule which proportionately distributes the total fertility rate by the age of mother. The 1990 county age-specific fertility rates were normalized to 1.0 children per woman. This produces probabilities of birth by a woman's age (Morgan and Chen, 1992) and represents the timing pattern of child-bearing. The 92 county-specific patterns were grouped into seven schedules used in the projections, which can be seen here and on the following pages. The counties assigned to each schedule appear next to the graphs.

Schedule A is the earliest timing pattern of child-bearing, and it is commonly found in rural counties. Schedule E is the latest timing pattern of child-bearing, and it is commonly found in suburban counties. Schedules B, C and D are interstitial patterns. The late pattern in Marion County was sufficiently different from other counties: it required its own schedule, F. Schedule G is reserved for the college counties of Delaware, Monroe, and Tippecanoe. The pattern of Vigo County, the home of Indiana State University, was not similar to the pattern of other college counties, and therefore it was not assigned this pattern.

Most counties do not retain their starting timing pattern throughout the life of the projection. For most counties, the median age of child-bearing increased between 1980 and 1990, and it is reasonable to assume that it will continue to do so. The timing patterns were adjusted based on the judgment of the analysts. *See Appendix B* for a detailed list of the timing patterns established by county for each projection cycle.

Before the T.F.R.s can be distributed by age, one subtle step is necessary. Because a woman will spend, on average, about half the five-year period in one age group and half in the next older one, the birth rate should be applied to an average of the five-year proportions for each age group. Therefore, using an adjacent cohort method the timing patterns were operationalized (Tarver, 1959). The table below provides a comparison of the two proportionate distributions.

Normalized Timing Pattern

Schedule	19 & Under	20-24	25-29	30-34	35-39	40-44

G	0.09	0.19	0.26	0.27	0.14	0.04	0.01

The expected number of births is multiplied by a sex ratio to determine the number of males and females. For the each county's projected births, 51.3% percent of births are assumed to be male and 48.7% female, the average rate for the state for 1989-91. This sex ratio was applied over the life of the series.

Applying the Projected Rates

Mechanically, the projections are carried out in the following manner. First, the base population is survived five years by multiplying the operational survival rates to its corresponding age-sex cohort. Second, resident rates are applied to the survived population. Finally, the future 0-4 age group is arrived at by applying the operational birth rates to the mid-point survived and migrated female household population, multiplying the number of births by the proportions of births of each sex, and surviving the infants to the end of the projection cycle. *See Population Projection Model on page 215.*

This procedure is carried out for each of the 92 counties for eight cycles of projections. The projected population and change components for the state as a whole are derived by summing county-level data: Indiana's projections employ a bottom-up model.

Uncertainty in Population Projections

The projections presented in this report for each county represent a consistent set which were developed using established methodology and delineated assumptions. Using this type of approach, the projections of one county can be easily compared to the projections of another county. However, the future population growth of any county is unlikely to follow the pattern set out in this report.

Relatively minor changes in economic, social, or demographic conditions in any county can cause actual population change to deviate significantly from the projected trends. Certain aspects of the 1980s may have included unique circumstances that are unlikely to reoccur (e.g., the recessions in manufacturing and farming during this period). Although our methodology does emphasize recent emerging trends in the population, it is dependent on these trends being discernible in the data.

Indiana Business Research Center
Indiana University School of Business

The Indiana Business Research Center (IBRC) has been an integral part of Indiana University's School of Business since 1925. The Center conducts and facilitates economic and demographic research efforts which contribute to the understanding and development of Indiana. For this purpose, the IBRC organizes and maintains extensive databases and develops systems and products for use by public and private agencies, both within and beyond Indiana.

Programs

ECONOMIC DEVELOPMENT INFORMATION NETWORK (EDIN)

Indiana's information utility is a network of people and computers offering a central source of timely data and resource information for more than 300 economic development offices, government agencies and private businesses. EDIN has become the critical link for rapid communication between the Indiana Department of Commerce and local economic development agencies.

INDIANA DATA CENTER PROGRAM

This successful Federal-State cooperative handles 72,000 Hoosier requests annually. This four-agency partnership between the Census Bureau and the IBRC, the Indiana State Library, and the Indiana Dept. of Commerce, provides local access to census data and expertise. These agencies work together to disseminate decision-making data via a network of 55 affiliates statewide, through *Census '90 Quick Release and Subject Reports*, and through EDIN.

INDIANA ENTERPRISE FILE

IEF is an initiative to organize and utilize company and employment data to provide better information about the performance of local economies, specific industries, and the state in general. The IEF database was created in partnership with the departments of Commerce and Employment & Training Services.

POPULATION STUDIES

Estimates and projections of the population and age of Hoosiers, by county, are critical components of government and business planning. The IBRC, in conjunction with the U.S. Census Bureau, produces estimates for counties annually. Projections, by 5-year age groupings and by gender, are produced twice each decade (Fall '93; Fall '98).

Publications

INDIANA BUSINESS REVIEW (IBR)

The IBR provides timely analysis on economic and business conditions in the state of Indiana each quarter. Since 1926, the major public source of forecasts of the international, national, state, and regional aspects of Indiana's economy and read by more than 3,000 subscribers.

THE INDIANA FACTBOOK

The premier publication of the IBRC, the third edition of the Factbook was published early in 1992. It is considered **the** statistical data reference for Indiana and its 92 counties and found in more than a thousand offices in Indiana and across the nation. **Call 1-800-842-6796 to order** from the IU Press.

INDIANA POPULATION REPORT (IPR)

An important quarterly resource for monitoring demographic trends and issues in Indiana. It is received by 1,500 educators, government officials, health administrators, legislators, business people, and planners.

INDIANA UPDATE

A monthly overview of Indiana economic trends providing current and concise information and analysis. First published in 1993, the *Update* targets Indiana business and economic development decision-makers.
